# This Class

## What You Will Learn:

- ▶ Deep Learning Concepts
  - ▶ Convolutional Neural Networks
  - ▶ Text Classification with Neural Networks

## Based On

Gareth James, Daniel Witten, Trevor Hastie and Robert Tibshirani:  
*An Introduction to Statistical Learning with Applications in R*. 2nd edition, corrected printing, June 2023. (ISLR2)

<https://www.statlearning.com>

Chapter 10

Kevin P. Murphy: *Probabilistic Machine Learning – An Introduction*.  
MIT Press 2022.

<https://probml.github.io/pml-book/book1.html>

Chapter 13, 14, 15

## Tensorflow Guides

<https://www.tensorflow.org/guide>

[https://www.tensorflow.org/tutorials/load\\_data/text](https://www.tensorflow.org/tutorials/load_data/text)

# Convolutional Neural Networks

## Task

- ▶ Image classification

## Problem

- ▶ Translation, scaling, and rotation of objects in images

## Solution

- ▶ Learning low-level and high-level "features" by learning a sequence of "filters" or "kernels"

# Convolution

## 1-Dimensional

Input	Kernel	Output
0 1 2 3 4 5 6	*      1 2	=      2 5 8 11 14 17

# Convolution [cont'd]

## Multi-channel 2D Convolution

Source: Murphy Fig. 14.9

*In a convolutional neural net layer, the convolution kernels are **trainable parameters**.*

# CNN Parameters

- ▶ Let the kernel be of size  $k \times l$
- ▶ Let the input be  $m$  channels
- ▶ Let the output be  $n$  channels
- ▶ Then, there are  $k \times l$  elements for each of the  $m$  input dimensions, i.e. a total of  $m \times k \times l$
- ▶ Then, there are  $m \times k \times l$  elements for each of the  $n$  output dimensions, i.e. a total of  $n \times m \times k \times l$
- ▶ Additionally, there are  $n$  bias terms, one for each output channel

**Example:** Let the kernel size be  $5 \times 5$  applied to an input with 3 channels and an output of 32 channels. Then, the CNN layer has  $32 \times 3 \times 5 \times 5 + 32 = 2432$  parameters.

# Hands-On Exercises

Calculate the number of trainable parameters for the following CNN layers:

- 1 A kernel of size  $4 \times 4$  operating on an input with 3 channels and an output of 8 channels.
- 2 A kernel of size  $2 \times 2$  operating on an input with 8 channels and an output of 16 channels.
- 3 A kernel of size  $3 \times 3$  operating on an input with 16 channels and an output of 4 channels.
- 4 A kernel of size  $5 \times 5$  operating on an input with 4 channels and an output with 4 channels.

Assume the previous four layers are part of the same neural network, what is the total number of trainable parameters?

# Convolution [cont'd]

## Striding and Padding

### Striding

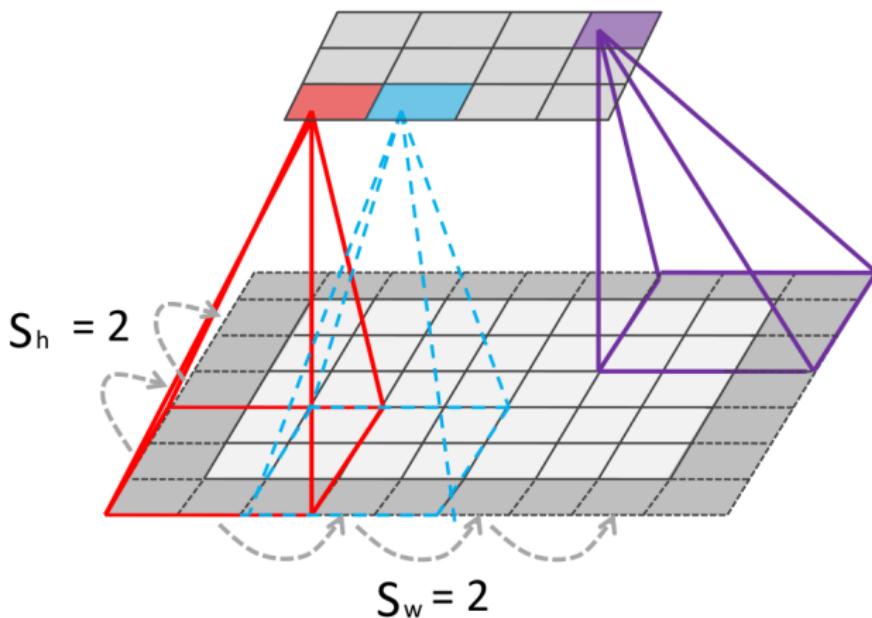

- ▶ Take "larger steps" moving the kernel
- ▶ Remove redundancy
- ▶ Increase efficiency

### Padding

- ▶ Surround the data matrix by zeros
- ▶ Increases weight of edge pixels
- ▶ Allows same-convolution, i.e. output size is the same as input size

# Convolution [cont'd]

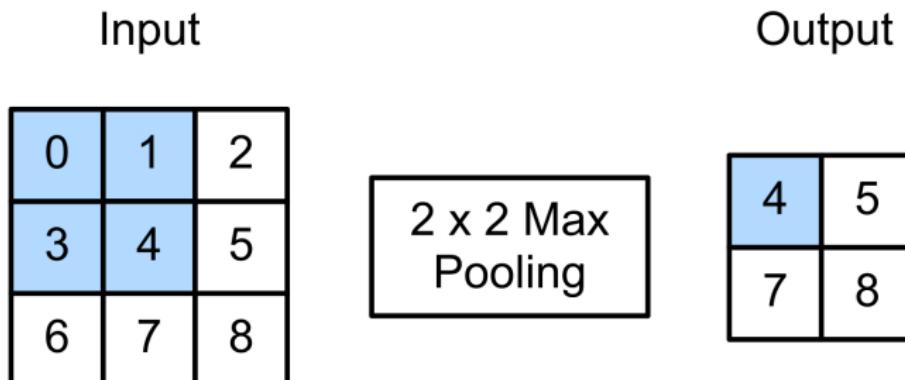

## Striding and Padding

Source: Murphy Fig. 14.8(b)

# Pooling

- ▶ Recognize location independent features
- ▶ Max pooling or average pooling
- ▶ Pooling layers have no trainable parameters

Source: Murphy Fig. 14.12

# Hands-On Exercises

- 1 Assume the following  $5 \times 5$  input matrix:

$$\begin{bmatrix} 1 & 2 & 3 & 2 & 1 \\ 2 & 3 & 2 & 1 & 3 \\ 3 & 2 & 1 & 3 & 2 \\ 2 & 1 & 3 & 2 & 1 \\ 1 & 3 & 2 & 1 & 3 \end{bmatrix}$$

and the following  $3 \times 3$  convolution kernel:

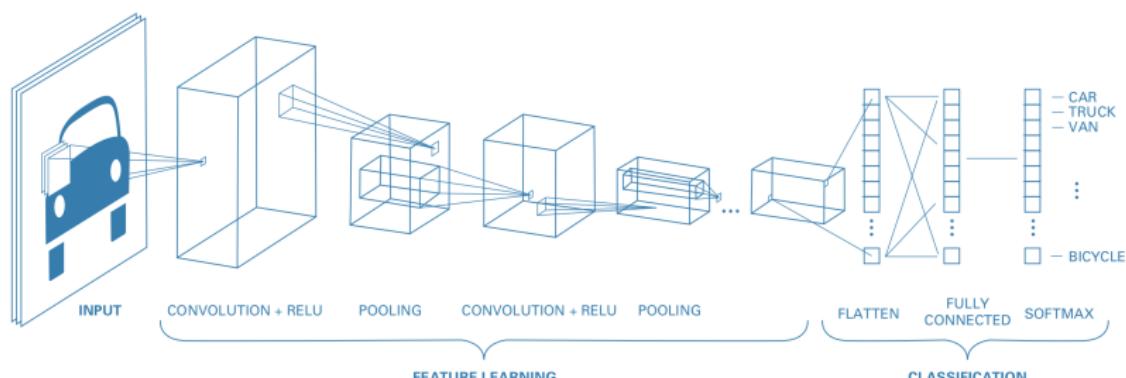

$$\begin{bmatrix} 1 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 1 \end{bmatrix}$$

Zero-pad the matrix with two zeros on all sides and using stride 2, calculate the convolution result. What are the dimensions of the convolution output?

- 2 Apply a  $2 \times 2$  max pooling layer to the result of the previous exercise.

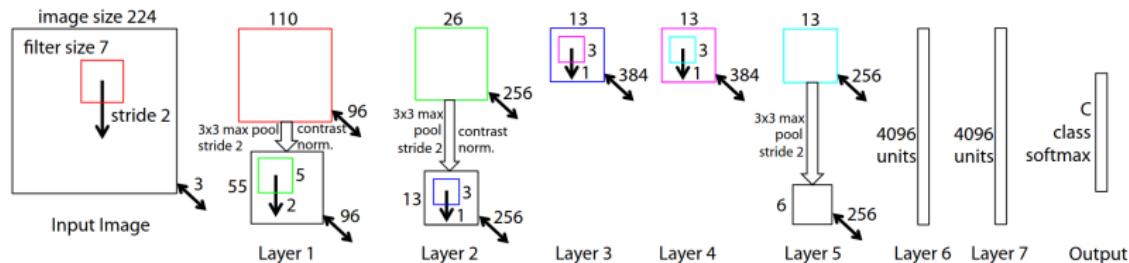

# CNN

- ▶ Multiple convolution and pooling (subsampling) layers
- ▶ Flatten final feature maps
- ▶ Multiple fully connected layers
- ▶ Softmax output

Source: Murphy Fig. 14.13

- ▶ Multiple convolutional kernels applied in parallel to the same image ("channels")

# CNN – Feature Maps

- ▶ ReLU'd and Pooled Convolution is a "**Feature Map**"
- ▶ Features maps at different layers identify different types of features
- ▶ Features form the input to the fully connected layers for classification
- ▶ Visualization e.g. with DeconvNet

# CNN in Keras

- ▶ 60,000 images,  $32 \times 32$  resolution, 3 channels
- ▶ 10 classes
- ▶ Latest error rate < 0.5%

# CNN in Keras

Import the data:

```
import tensorflow as tf
from tensorflow.keras import datasets, layers, models
import datetime

(train_images, train_labels), \
(test_images, test_labels) \
    = datasets.cifar10.load_data()

# Normalize pixel values to be between 0 and 1
train_images, test_images = \
train_images / 255.0, test_images / 255.0
```

# CNN in Keras

Create a simple convolutional model:

```
model = models.Sequential()
model.add(layers.Conv2D(8, (3, 3), \
    activation='relu', input_shape=(32, 32, 3)))
model.add(layers.MaxPooling2D((2, 2)))
model.add(layers.Conv2D(16, (3, 3), \
    activation='relu'))
model.add(layers.MaxPooling2D((2, 2)))
model.add(layers.Conv2D(16, (3, 3), \
    activation='relu'))
```

Add dense (fully-connected) layers for classification. There are 10 target classes:

```
model.add(layers.Flatten())
model.add(layers.Dense(32, activation='relu'))
model.add(layers.Dense(10))

model.summary()
```

# CNN in Keras

Set up for TensorBoard:

```
log_dir = "./tensorboard_logs/" + \
    datetime.datetime.now().strftime("%Y%m%d-%H%M%S")
tensorboard_callback = \
    tf.keras.callbacks.TensorBoard(log_dir=log_dir,
        histogram_freq=0)
```

Compile and train the model:

```
model.compile(optimizer='adam',
    loss=tf.keras.losses \
        .SparseCategoricalCrossentropy(from_logits=True),
    metrics=['accuracy'])

history = model.fit(train_images, train_labels,
    epochs=10,
    validation_data=(test_images, test_labels),
    callbacks=[tensorboard_callback])
```

# Other Computer Vision Tasks for CNNs

## Object Detection

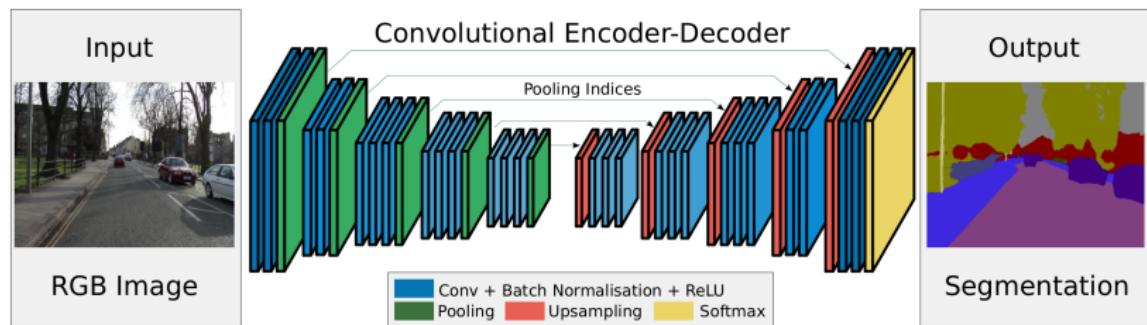

Source: Murphy Fig. 14.27

$$f_{\theta} : R^{H \times W \times K} \rightarrow [0, 1]^{A \times A} \times \{1, \dots, C\}^{A \times A} \times (R^4)^{A \times A}$$

For each anchor box, learn the object presence probability, the object category and two offset vectors to be added to the center of the box to the top left and bottom right corners.

# Other Computer Vision Tasks for CNNs

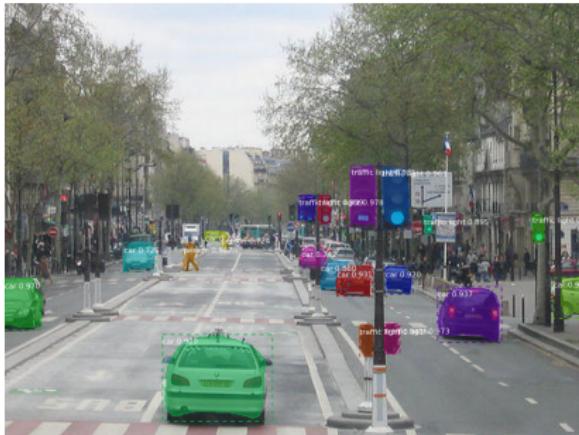

## Semantic Segmentation

Source: Murphy Fig. 14.29

Using an **encoder-decoder** or **U-net** network to identify the class of each pixel in an image.

# Other Computer Vision Tasks for CNNs

[https://github.com/matterport/Mask\\_RCNN](https://github.com/matterport/Mask_RCNN)

Perform semantic segmentation within each anchor box from object detection to identify foreground (object) and background.

# Text Classification using CNN

Import packages:

```
import collections
import pathlib
import datetime

import tensorflow as tf
from tensorflow.keras import layers
from tensorflow.keras import losses
from tensorflow.keras import utils
from tensorflow.keras.layers import TextVectorization
```

# Text Classification using NN [cont'd]

Download the Stack Overflow dataset:

```
data_url = \
'http://download.tensorflow.org/ \
data/stack_overflow_16k.tar.gz'
# Get the data
dataset_dir = \
utils.get_file(origin=data_url,
               untar=True,
               cache_subdir='stack_overflow')
# Remember where we put it
dataset_dir = pathlib.Path(dataset_dir).parent
train_dir = dataset_dir/'train'
test_dir = dataset_dir/'test'
# Print a sample
sample_file = train_dir/'python/1755.txt'
with open(sample_file) as f:
    print(f.read())
```

## Text Classification using NN [cont'd]

Read the training data portion and split into training and validation set

```
raw_train_ds = \  
    utils.text_dataset_from_directory(  
        train_dir, batch_size=32,  
        validation_split=0.2,  
        subset='training', seed=42)  
  
raw_val_ds = \  
    utils.text_dataset_from_directory(  
        train_dir, batch_size=32,  
        validation_split=0.2,  
        subset='validation', seed=42)
```

Read the test set portion of the dataset:

```
raw_test_ds = utils.text_dataset_from_directory(  
    test_dir, batch_size=32)
```

# Text Classification using NN [cont'd]

## Pre-Processing

- ▶ **Standardization:** Remove punctuation, remove HTML elements, etc.
- ▶ **Tokenization:** Split strings to tokens (e.g. sentences into words on whitespace)
- ▶ **Vectorization:** Convert tokens into numbers for input into a neural network

## Bag-of-Word Model

- ▶ Counts frequency of words/tokens
- ▶ Neglects order

```
John likes to watch movies. Mary likes movies too.  
{ "John":1, "likes":2, "to":1, "watch":1,  
  "movies":2, "Mary":1, "too":1}
```

# Text Classification Using NN [cont'd]

Use the Keras TextVectorization pre-processing layer:

```
multi_hot_vectorize_layer = TextVectorization(  
    max_tokens=10000,  
    standardize='lower_and_strip_punctuation',  
    split='whitespace',  
    output_mode='multi_hot')  
  
# Get only the text from the training set  
train_text = raw_train_ds.map(lambda text, labels: text)  
multi_hot_vectorize_layer.adapt(train_text)
```

## Text Classification Using NN [cont'd]

- ▶ The "multi-hot" vectorization layer outputs a single integer array per mini-batch, containing 1s in all elements where the token mapped to that index exists at least once in the mini-batch item.

```
# Retrieve a batch from the dataset
text_batch, label_batch = next(iter(raw_train_ds))

# Applying the text vectorization layer
# to the first example and print its output
print(text_batch[0])
print(list(multi_hot_vectorize_layer(text_batch[0]).numpy()))
```

# Text Classification Using NN [cont'd]

Define a simple model, set loss function, optimizer and a metric to collect:

```
multi_hot_model = tf.keras.Sequential([
    multi_hot_vectorize_layer,
    layers.Dense(4))

multi_hot_model.compile(
    loss= \
    losses.SparseCategoricalCrossentropy(from_logits=True),
    optimizer='adam',
    metrics=['accuracy'])
```

## Text Classification Using NN [cont'd]

Train the model for 25 epochs, showing validation set accuracy after each epoch:

```
multi_hot_model.fit(raw_train_ds,  
                     validation_data=raw_val_ds,  
                     epochs=25)
```

# Hands-On Exercises

Adapt the network architecture to identify the impact on training and validation performance of the following:

- 1 Vocabulary size (originally 10 000)
- 2 Number of layers (originally 1)

Comment on your findings and identify the best model.

# Text Classification Using CNN [cont'd]

Use the Keras TextVectorization pre-processing layer, this time with integer outputs:

```
int_vectorize_layer = TextVectorization(  
    max_tokens=10000,  
    standardize='lower_and_strip_punctuation',  
    split='whitespace',  
    output_mode='int')  
  
# Get only the text from the training set  
train_text = raw_train_ds.map(lambda text, labels: text)  
# Adapt the layer  
int_vectorize_layer.adapt(train_text)
```

# Text Classification Using CNN [cont'd]

- ▶ The "int" vectorization layer outputs integer indices, one integer index per split string token.

```
# Retrieve a batch from the dataset
text_batch, label_batch = next(iter(raw_train_ds))

# Applying the text vectorization layer
# to the first example and print its output
print(text_batch[0])
print(list(int_vectorize_layer(text_batch[0]).numpy()))
```

# Word Embeddings

## One-hot encoding

	cat	mat	on	sat	the
<b>the</b> =>	0	0	0	0	1
<b>cat</b> =>	1	0	0	0	0
<b>sat</b> =>	0	0	0	1	0
...	...	...	...	...	...

## A 4-dimensional embedding

<b>cat</b> =>	1.2	-0.1	4.3	3.2
<b>mat</b> =>	0.4	2.5	-0.9	0.5
<b>on</b> =>	2.1	0.3	0.1	0.4
...	...	...	...	...

[https://www.tensorflow.org/text/guide/word\\_embeddings](https://www.tensorflow.org/text/guide/word_embeddings)

- ▶ Embedding matrix elements are **learnable parameters**
- ▶ Dimension reduction
- ▶ May be useful to measure similarity of terms

## Text Classification Using NN [cont'd]

Define a 1D-CNN model, set loss function, optimizer and a metric to collect:

```
int_model = tf.keras.Sequential([
    int_vectorize_layer,
    layers.Embedding(10001, 64, mask_zero=True),
    layers.Dropout(0.5),
    layers.Conv1D(filters=64, kernel_size=5, \
        padding="valid", activation="relu", strides=2),
    layers.GlobalMaxPooling1D(),
    layers.Dense(4)
])

int_model.compile(
    loss= \
    losses.SparseCategoricalCrossentropy(from_logits=True),
    optimizer='adam',
    metrics=['accuracy'])
```

# Text Classification Using NN [cont'd]

Train the model for 25 epochs:

```
int_model.fit(raw_train_ds,  
              validation_data=raw_val_ds,  
              epochs=25)
```

# Hands-On Exercises

Adapt the network architecture to identify the impact on training and validation performance of the following:

- 1 Vocabulary size (originally 10 000)
- 2 Embedding size (originally 64)
- 3 Dropout probability (originally 0.5)
- 4 Convolution kernel size (originally 5)
- 5 Number of convolution filters (originally 64)
- 6 Convolution stride (originally 2)
- 7 Number of 1D-Conv layers (originally 1)

Comment on your findings and identify the best model.
